Critical Care Nutrition: Systematic Reviews March 2021

### 6.3 Enteral Nutrition (Other): Continuous vs. Other Methods of Administration

Question: Does continuous administration of enteral nutrition compared to other methods of administration result in better outcomes in critically ill patients?

**Summary of evidence:** There were 6 level 2 studies comparing continuous 24-hour enteral feeding to intermittent or bolus feeds. In the non-continuous EN arm, five of the studies (Steevens 2002, Serpa 2003, Chen 2006, MacLeod 2007 and McNelly 2020) gave boluses of enteral nutrition (EN) over 15-60 minutes multiple times a day, whereas 1 study (Bonten 1996) gave EN continuously over 18 hours.

**Mortality:** When the four studies reporting mortality were meta-analyzed, continuous feeding was associated with trend towards a reduction in overall mortality compared to intermittent/bolus feeds (RR 0.77, 95% CI 0.53, 1.13, p=0.18, test for heterogeneity  $I^2 = 0\%$ , figure 1).

**Infections:** Continuous feeding had no significant effect on pneumonia (RR 1.53, 95% CI 0.59, 3.97, p=0.38, test for heterogeneity I<sup>2</sup>=79%, figure 2) or aspiration (RR 0.33, 95% CI 0.04, 2.98, p=0.33, test for heterogeneity I<sup>2</sup> = 0%, figure 3) when compared to intermittent/bolus feeding.

**LOS & Ventilator days:** When the three studies (Serpa 2003, MacLeod 2007, McNelly 2020) that had ICU LOS available in mean and SD were aggregated, there was no difference found between the groups (WMD -1.17, 95% CI -4.36, 2.02, p=0.47, test for heterogeneity I<sup>2</sup>=0%, figure 4). Chen et al reported on the number of patients with ICU LOS less than or equal to 21 days and greater than 21 days and found a trend towards an increase in frequency of ICU LOS >21 days in the group receiving continuous feeds (p=0.15). Only one study reported hospital LOS and duration of mechanical ventilation and there were no differences between the continuously or intermittently fed groups (McNelly 2020, p=0.91 and p=0.25 respectively). Chen et al 2006 reported on the number of patients extubated after 21 days and they found a significantly higher number of patients receiving intermittent feeds were free of ventilator support after 21 days (p=0.002). MacLeod 2007 reported on the number of patients extubated prior to day 7 and found no difference between groups (p=0.58).

**Other complications:** Two studies (Steevens 2002 and MacLeod 2007) reported on total number of patients who developed diarrhea during the study and when the data was aggregated, there was a trend towards reduced diarrhea in the continuously fed group (RR 0.48, 95% CI 0.18, 1.27, p=0.14, test for heterogeneity I<sup>2</sup>=0%; figure 5). Serpa et al 2003 reported on the daily occurrence of diarrhea and found no significant differences between groups (p>0.05) while McNelly 2020 reported a trend towards a reduction in feeding interruption due to diarrhea in the intermittent fed group compared

Critical Care Nutrition: Systematic Reviews March 2021

to the continuous group (p=0.05). When the data from the three studies that reported the number of patents with high gastric volumes were aggregated, there were no significant differences between the two groups (RR 0.64, 95% CI 0.31, 1.31, p=0.22, test for heterogeneity I<sup>2</sup>=0%; figure 6). Two other studies reported on varying descriptions of gastric residual volumes with or without vomiting and found no significant differences between continuous or intermittent feedings (Chen 2006 p=0.097 and McNelly 2020 p=0.21). Intermittent feeding resulted in lower incidences of feeding interruption due to nausea and vomiting (p=0.02) but a higher incidence of abdominal distension (p=0.02) as compared to continuous feeding in the McNeely 2020 study.

Three studies reported on percentage goal feeds or calories achieved but not in mean and standard deviation, therefore, the data could not be aggregated. Two studies (Steevens 2002 and MacLeod 2007) found no significant difference between groups (p=NS and p>0.05, respectively) however McNelly 2020 reported that intermittent feeds were associated with achieving a significantly higher percentage of goal calories and protein compared to continuous feeding (p<0.001). In the same study, there were no differences in the preservation of muscle mass between the two groups.

#### **Conclusion:**

Compared to intermittent/bolus feedings, providing EN continuously over 24 hours,

- 1) May be associated with a reduction in overall mortality in ICU patients.
- 2) Is not associated with a difference in aspiration or pneumonia. There is insufficient evidence to comment on the occurrence of other infections.
- 3) Is not associated with a difference in ICU LOS.
- 4) Is inconclusive with respect to its impact on diarrhea.
- 5) Is not associated with a difference in nutritional adequacy or elevated gastric residual volumes.
