## 4.1c Composition of EN: Glutamine

## **Question:**

Compared to standard care, does glutamine-supplemented enteral nutrition result in improved clinical outcomes in critically ill patients?

**Summary of Evidence**: There were 9 level 2 studies and 3 level 1 studies, 5 of which were in burn patients (Garrel 2003, Zhou 2003, Peng 2004, Pattanshetti 2009, lamsirisaengthong 2017), 3 in trauma patients (Houdijk 1998, Brantley 2000 and McQuiggan 2008) and the remaining 4 were in mixed ICU patients.

Mortality: When the data from all the 10 trials that reported on mortality were aggregated, there was no statistically significant difference in mortality between the groups receiving glutamine supplemented EN or not (RR = RR 0.97, 95% CI 0.70, 1.34, p =0.84, test for heterogeneity  $I^2$  = 10%) (figure 1). Subgroup analyses of the 5 studies of trauma patients showed that glutamine supplemented EN had no significant effect on hospital mortality (RR 1.03, 95% CI 0.54, 1.97, p = 0.92, test for heterogeneity  $I^2$  = 0%) (figure 2). In the 5 studies of burn patients, patient deaths in hospital occurred in 4 studies (Garrel 2003, Zhou 2003, Pattanshetti 2009, lamsirisaungthong 2017) and a significant reduction in hospital mortality was associated with the use of enteral glutamine (RR 0.26, 95% CI 0.08, 0.80, p =0.02, test for heterogeneity  $I^2$  = 0%) (figure 3).

Infections: Of the 3 level 2 studies and 1 level 1 study that reported on the total number of patients with infectious complications, there was no statistically significant difference in infectious complications with glutamine supplemented EN ( RR 0.93, 95% CI 0.79, 1.10, p = 0.39, test for heterogeneity  $I^2 = 0\%$ ) (figure 4). In the one study in burn patients that reported on patients with infections (Zhou 2003), glutamine supplemented EN was associated with a significant reduction in infectious complications while in one burn study (Garrel 2003) a significant reduction was seen in the number of positive blood cultures. In the subgroup of trauma patients, there was a trend towards a reduction in infections in the groups that received enteral glutamine (RR 0.85, 95% CI 0.68, 1.06, p = 0.15, test for heterogeneity  $I^2 = 0\%$ ) (figure 5).

Length of Stay: There were 7 level 2 studies and 1 level 1 study that demonstrated a significant reduction in length of hospital stay (WMD (weighted mean difference) - 4.69, 95% CI -8.19, -1.18, p = 0.009, test for heterogeneity  $I^2 = 44\%$ ) (figure 6). A stronger effect was seen in the subgroup of burn patients (WMD -8.18, 95% CI -12.69, -3.67, p = 0.0004, test for heterogeneity  $I^2 = 30\%$ ) (figure 8) but not seen in the subgroup of trauma patients (WMD -0.54 95% CI -0.54 CI -0.

**Mechanical ventilation**: Only 2 studies reported on mechanical ventilation as means and standard deviation and when the data were aggregated, enteral glutamine had no effect on duration of mechanical ventilation (WMD -0.10, 95% CI -0.93, 0.73, p =0.82).

Critical Care Nutrition: Systematic Reviews www.criticalcarenutrition.com

December 2018

## **Conclusions:**

- 1) Glutamine supplemented enteral nutrition is associated with a reduction in mortality in burn patients, but inconclusive in other critically ill patients.
- 2) Glutamine supplemented enteral nutrition may be associated with a reduction in infectious complications in burn and trauma patients.
- 3) Glutamine supplemented enteral nutrition is associated with a reduction in hospital length of stay in burn and other critically ill patients but not in trauma patients and may be associated with a reduction in ICU LOS in trauma patients.

Level 1 study: if all of the following are fulfilled: concealed randomization, blinded outcome adjudication and an intention to treat analysis. Level 2 study: If any one of the above characteristics are unfulfilled
